PATENT APPLICATION

A PBX SWITCH INCORPORATING METHODS AND APPARATUS FOR
AUTOMATICALLY DETECTING CALL APPEARANCE VALUES FOR EACH
PRIMARY DIRECTORY NUMBER ON A BASIC RATE INTERFACE

10

BACKGROUND OF THE INVENTION

1. Field of the Invention

15

The invention relates to the Basic rate
Interface (BRI) for the Integrated services Digital
Network (ISDN). More particularly, the invention relates
to a PBX switch which incorporates methods and apparatus
for automatically detecting call appearance values for
each Primary Directory Number (PDN) in an ISDN BRI.

20

2. Brief Description of the Prior Art

25

The Basic Rate Interface (BRI) of ISDN service
consists of two B channels, each having a bandwidth of
64kbits/s and one D channel having a bandwidth of
16 kbits/s. Generally, each of the B channels can be
used to support one voice connection or one data
connection, or the two B channels can be used together to
support one 128 kbits/s data connection. The D channel
is used for signaling between the customer equipment

30

(terminal equipment or TE) and the central office in order to setup, manage, and tear down connections. Each B channel is assigned a directory number (DN), i.e. a ten digit telephone number.

5

Two signaling protocols are used with BRI ISDN in order to establish and maintain connections: The layer 3 Q.931 protocol and the LAPD (link access protocol for the D channel). Q.931 messages are carried within an LAPD frame on the D channel. A Q.931 message includes several octets specifying protocol discriminator, length of call reference value, call reference value, message type, etc. Some of the messages sent using the Q.931 protocol include SETUP, SETUP ACKNOWLEDGE, CALL PROCEEDING, CONNECT, CONNECT ACKNOWLEDGE, RELEASE, RELEASE COMPLETE, HOLD, and HOLD ACKNOWLEDGE.

The 1999 Version of the Bellcore National ISDN BRI Terminal Equipment (TE) Generic Guidelines (SR-4620, Issue 1, December 1996) specifies guidelines for implementing many ISDN features. Among these features is a feature known as Call Appearance.

With Call Appearance, a single BRI can respond to up to 128 DNs. Moreover, customer equipment can be designated with up to 128 terminal endpoint identifiers (TEIs) each of which identifies a specific telephone or device connected to the BRI. Using Call Appearance and TEIs, each of up to 128 telephones or other devices

connected to a single BRI can be provided with a separate
DN. Further, each of the telephones connected to the
single BRI can be configured as multiline phones
responding to several DNs using electronic key telephone
5 service (EKTS).

EKTS permits a number of illuminated keys on a
telephone set to be addressed by the central office to
indicate virtual additional lines. Those skilled in the
10 art will appreciate that regardless of the number of Call
Appearances, the single BRI only supports two active
telephone calls at one time. More calls may be placed
❖ on hold❖ at the central office, using Q.931 signaling,
but only two calls may be active at one time.

15 Separate Call Appearance values (0-63) are
assigned to each B channel according to the service
contract chosen by the customer. As mentioned above, two
DNs are assigned to the BRI. This is the case when both
20 B channels have a Call Appearance value of 0. These DNs
are referred to as the primary directory numbers (PDNs).
Each PDN may have a Call Appearance value other than 0
(up to 63) associated with it depending on the customer
service contract. The call appearance value indicates
25 the number of additional DNs associated with the B
channel identified by the PDN.

As mentioned above, the Call Appearance values are in the range 0 to 63 for each B channel. The values used and the specific meaning of each Call Appearance value are defined during the ordering process in an agreement between the customer and the Central Office.

The different values are usually used to handle Central Office features (e.g. call waiting indication, voice mail message, call forwarding) and multiple calls for same B channel. In addition, choosing a special arrangement of Call Appearances and directory numbers allows a PBX to offer the equivalent of Direct Inward Dial capability over standard BRI lines.

Table 1 below illustrates an example of three BRI lines with multiple Call Appearances and shared multiple directory numbers. The main directory number for each B channel is italicized.

CA	Circuit 1		Circuit 2		Circuit 3	
	B1	B2	B1	B2	B1	B2
01	555-4001	555-4001	555-4001	555-4001	555-4001	555-4001
02	555-4002	555-4002	555-4002	555-4002	555-4002	555-4002
03	555-4003	555-4003	555-4003	555-4003	555-4003	555-4003
04	555-4004	555-4004	555-4004	555-4004	555-4004	555-4004
05	555-4005	555-4005	555-4005	555-4005	555-4005	555-4005
06	555-4006	555-4006	555-4006	555-4006	555-4006	555-4006

Table 1

Incoming calls for any of the six directory numbers are presented by the Central Office on all associated channels with the same Call Appearance value. In the PBX, each of the Call Appearances is assigned to a

different station.

According to the state of the art, customer equipment must be manually configured with a service
5 profile identifier (SPID) as well as the number of Call
Appearances for each PDN. The correct configuration of
BRI trunks and telephone equipment at the customer's
premises requires specialized service engineers. The
equipment must be configured for Call Appearance Call
10 Handling (CACH) based on documentation provided by the
central office. The available documentation is often not
accurate or not up to date during the installation and
(remote) configuration of the telephone equipment. A
wrong configuration could leave trunk interfaces unusable
15 by the customer.

The configuration of customer equipment is even
more difficult when multiple BRIs are involved. For
example, many PBX systems utilize multiple ISDN BRIs as
20 an alternative to multiple individual DS1 or more
expensive T1 connections. The Siemens Hicom 150 provides
up to 16 BRIs through four interface cards, each of which
supports four ISDN BRIs. Configuring a Hicom 150 could
conceivably require configuring up to 2,048 Call
25 Appearances (32*64).

SUMMARY OF THE INVENTION

5 It is therefore an object of the invention to
provide methods and apparatus whereby customer equipment
can be easily configured for ISDN Call Appearances.

10 It is also an object of the invention to
provide methods and apparatus for accurately configuring
customer equipment for ISDN Call Appearances.

15 It is another object of the invention to
provide methods and apparatus for configuring customer
equipment for ISDN Call Appearances without the aid of a
service technician.

20 It is yet another object of the invention to
provide methods and apparatus for quickly configuring
customer equipment for ISDN Call Appearances.

It is another object of the invention to
provide methods for automatically configuring call
appearance values in a PBX device.

25 It is still another object of the invention to
provide a PBX device with the capability of self-
configuring call appearance values.

In accord with these objects which will be discussed in detail below, the methods according to the invention include generating a call from one PDN to the other in the same BRI circuit and monitoring the message exchange on the D channel to obtain Call Appearance information. The central office provides the first valid Call Appearance (via the D channel) to the PDN being called and this value is stored in the called PDN database.

10

To get all the provided Call Appearance values for each channel, the first call is placed on hold. A new call is generated from one PDN to the other in the same BRI circuit. The central office provides the second valid Call Appearance to the PDN being called and this value can also be stored in the called PDN database. This process is repeated for both channels as long as the central office offers new Call Appearance values.

15

The method of the invention requires only the use of standard network protocol procedures needed for standard call processing. This means that the method is not dependent of supplementary BRI services being offered by the central office that support terminal parameter downloading.

20

25

Thus, the method can be implemented in any existing or planned telephone equipment with no hardware and small software enhancement effort. The method is

able to provide the Call Appearance values for BRI trunks supported by the telephone equipment, independent of the central office to which the customer's premises is connected.

5

The presently preferred embodiment is based on a modified Hicom 150. All of the hardware and low level software functionality needed to implement the inventive method is already available via existent function calls or via defined mailbox messages at the Device Handler, Database or Loadware level.

The new procedure is preferably located at the Device Handler and activated when the TMQ4 line card start-up is finished, layer 1 and layer 2 are up, and TEI and SPID handling are successfully accomplished. However, the methods of the invention can be implemented in virtually any ISDN customer equipment whether it be voice equipment or data equipment.

20

Combining the methods of the invention with known methods for determining the SPID of BRI trunks, a stand-alone test gear to identify BRI characteristics can be built.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a high level flow diagram of a simple layer 3 message exchange according to the methods of the invention.

FIG. 2 is a high level flow diagram of a more elaborate layer 3 message exchange according to the methods of the invention.

FIG. 3 is a high level block diagram illustrating an apparatus for performing the methods of the invention.

FIG. 4 is a high level block diagram of a PBX switch incorporating the methods of the invention.

DETAILED DESCRIPTION

Turning now to FIG. 1, a simple layer 3 message exchange between customer equipment and the central office (CO) is illustrated whereby call appearance information is obtained during a call from PDN1 to PDN 2.

A SETUP message is sent to the CO with call reference (CR) equal to 1. The CO responds with a CALL PROCEEDING message with CR=81 and a SETUP message with CR=2 and call appearance (CA) equal-1. The call is terminated by the customer equipment sending a RELEASE command with CR=82

and the CO responding with RELEASE COMPLETE with CR=81.

The above message exchange illustrates how CA information is obtained from the CO during a single call.

5 According to the methods of the invention, multiple calls are made to the same PDN until all CAs are obtained.

FIG. 2 illustrates in a simplified manner how this is accomplished.

10 In the first three message exchanges in FIG. 2, a call is setup from PDN1 to PDN2 and the CA=1 is obtained. A CONNECT ACK with CR=2 is received when the PDN2 accepts the call. PDN1 then puts the first call on hold with HOLD (CR=1) message and the hold is
15 acknowledged with the HOLD ACK (CR=81) message. Though not illustrated in FIG. 2, the PDN1 now initiates a second call to PDN2 which results in a call waiting message on the PDN2 line together with a CA value which will be stored, assuming that PDN2 has at least 2 CAs.

20

Upon receiving the second call, PDN2 places the first call on hold using the HOLD (CR=82) message which is acknowledged with the HOLD ACK (CR=2) message. Now that two CAs have been obtained, PDN1 will repeat the
25 process putting the latest call on hold and initiating another call until PDN2 is unable to accept any more calls, i.e. PDN1 gets a busy signal.

After the process described above is completed with PDN1 calling PDN2, it is repeated with PDN2 calling PDN1. In the case of a PBX such as the Hicom 150, the process is repeated for each BRI coupled to the PBX.

5

As mentioned above, the presently preferred embodiment of the invention is embodied as software or firmware in the Siemens Hicom 150 PBX device. However, it will be appreciated that the methods of the invention can be embodied in any TE coupled to a BRI. FIG. 3 illustrates a generic hardware embodiment of the invention.

Referring now to FIG. 3, the apparatus 10 includes a logic unit 12 which is coupled to a call appearance database 14, a directory number memory 16, the BRI B channels 18, and the BRI D channel(s) 20. The logic causes the B channels to call one another using the PDN data provided in the DN memory and monitors the D channel to collect call appearance data which is stored in the database.

Those skilled in the art will appreciate that the database 14 and the memory 16 may be the same memory device and that the CA data collected in the database may be forwarded to another par of TE for appropriate use. It will also be appreciated that the logic may be embodied as a processor with associated program memory, as an Application Specific Integrated Circuit (ASIC), as

a Field Programmable Gate Array (FPGA), as a state machine, or any other appropriate device for carrying out the methods of the invention.

5 Referring now to FIG. 4, a PBX switch 100 according to the invention is a modified Siemens Hicom 150. The switch 100 includes a plurality of trunk cards 102, each being coupled to a plurality of ISDN BRI trunk lines 104, and plurality of subscriber line boards 106,
10 each being coupled to a plurality of subscriber lines 108.

 The switch is operated by main software 110 which includes a data base 112, a device handler 114, and
15 a call processing switching unit 116. As mentioned above, all the hardware and low level software functionality needed to implement the inventive method is already available in the Hicom 150 via existent function calls or via defined mailbox messages at Device Handler,
20 Database or Loadware level. The new procedure is preferably located at Device Handler 114 and is activated when the trunk boards start-up is finished, layer 1 and layer 2 are up, TEI and SPID handling are successfully accomplished.

25

 As mentioned above, the methods of the invention requires only the use of standard network protocol procedures needed for standard call processing.

This means that the method is not dependent of supplementary BRI services being offered by the central office that support terminal parameter downloading. Thus, the method can be implemented in any existing or
5 planned telephone equipment with no hardware and small software enhancement effort. The method is able to provide the Call Appearance values for BRI trunks supported by the telephone equipment, independent of the central office to which the customer's premises is
10 connected.

Those skilled in the art will appreciate that the methods of the invention can be combined with known methods for determining the SPID of BRI trunks to create
15 a stand-alone test gear to identify BRI characteristics. However, the primary intention of the invention is to provide a means whereby telephone equipment coupled to one or more BRIs can be quickly self-configured without the aid of a technician.

20 There have been described and illustrated herein methods and apparatus for automatically identifying call appearance values in an ISDN BRI. While
25 particular embodiments of the invention have been described, it is not intended that the invention be limited thereto, as it is intended that the invention be as broad in scope as the art will allow and that the specification be read likewise. It will therefore be

appreciated by those skilled in the art that yet other modifications could be made to the provided invention without deviating from its spirit and scope as so claimed.
